Network Operations Handbook

1 Scope

This handbook defines how the operations team monitors, maintains and restores the production network. It applies to every datacentre, to the wide area links and to the services that depend on them.

2 Monitoring

2.1 Alert levels

Alerts are classified in three levels. A warning requires attention during office hours, a critical alert must be acknowledged within fifteen minutes, and a major incident triggers the on-call manager.

Level	Acknowledge within	Escalation
Warning	4 hours	Team lead
Critical	15 minutes	On-call engineer
Major	5 minutes	On-call manager

2.2 Health checks

Every service exposes a health endpoint which the monitoring system queries each thirty seconds. The checks cover the following points:

- link status and packet loss on every uplink
- latency between the datacentres
- certificate expiry dates
- disk usage of the log collectors

3 Recovery

3.1 Failover

If the primary datacentre becomes unreachable, traffic must failover to the secondary datacentre within ninety seconds. The procedure is automatic, and the operator only verifies the result with the command below.

```
$ netctl failover status --site secondary
active: true
lag_seconds: 12
```

3.2 Post-incident review

A written review is produced within five working days after each major incident. It lists the timeline, the root cause, the customer impact and the corrective actions, each with an owner and a due date.
